Review

CSS Transitions are a powerful tool for providing visual feedback to users. We've learned a lot about transitions, so let's review:

CSS Transitions have 4 components:

A *property* that will transition.

The *duration* which describes how long the transition takes.

The *delay* to pause before the transition will take place.

The *timing function* that describes the transition's acceleration.

A simple transition can be described with a property and a duration, which can be written like this:

```
transition-property: color;
transition-duration: 1s;
```

Many properties' *state changes*can be transitioned, including color, background color, font size, width, and height. `all` is also a valid transition property that causes every changing property to transition.

The shorthand property `transition` can be used to describe all four components of a transition at once. By using the comma (`,`) operator, many transitions can be described in one CSS rule.
